Sociobiology views much social behavior, including aggressive behavior, as genetically determined. Consider Darwin's theory of evolution. Darwin held that many more individuals are produced than can find food and survive into adulthood. A struggle for survival follows. Those individuals who possess characteristics that provide them with an advantage in the struggle for existence are more likely to survive and contribute their genes to the next generation. In many species, such characteristics include aggressiveness. B Artificial stimulation of the hypothalamus results in aggression in animals. C Animals behaving aggressively show increased activity in the hypothalamus. D Animals who lack a hypothalamus display few aggressive tendencies. Among intensely social animals, the social group, the dominance hierarchy, the superordinate level, clearly constitutes a form of extended cooperation. Within that group, however, that cooperative space, the subordinate level, dominance striving takes place. The consequences of extended social being, however, are more indirectly associated with aggression regulation, and appear related to the function of neural circuits that mature later, in a predictable, regulated and orderly social environment. If human children are socialized, within such an environment, they learn socially-acceptable but more complex alternatives to violence. Animal instincts Evolution can explain why humans exhibit aggression because it is a primal emotion like any other, experts say. Gang violence is a good example of competition for resources gone haywire, though while a gang member's desire for more things, money or partners causes problems now, it may have been the key to their survival 100,000 years ago. Aggression in few animals goes beyond protecting one's territory, mates, offspring and food there is some evidence that domestic dogs and chimpanzees do hold grudges, said Carrier but human violence has evolved to stem from less typical sources. "For example revenge killings, and the cultural institutions that support and restrain it, shape human aggression in new ways," said Cashdan.

Territorial aggression is a major component of social systems that fluctuates seasonally as well as within breeding seasons. The plasticity in this behavior in response to a variety of physical and social aspects of the environment may reflect the multitude of selection pressures that can shape territorial behavior. In the appropriate contexts, territorial aggression is highly beneficial for gaining access to resources. The study of mechanisms controlling these behaviors is proving to be rewarding because of the striking plasticity of the behavior. New neural mechanisms are continually being discovered that reveal the complexity of control of aggression. Aggressive behavior in animals, Social behavior in animals, Competition (Biology). Read more. Read less. Apparently inconsistent with the CLASH model, animal research relates predictable environments to rigid routine behaviors and aggression. However, our work on evolutionary and neural adaptations to (un)predictable environments may be able to reconcile the CLASH model with the animal research, but also suggests complexities beyond the dichotomous approach of CLASH. Topics. Competition (Biology), Aggressive behavior in animals, Social behavior in animals. Publisher. Washington : Smithsonian Institution Press. Competition is an interaction between organisms or species in which both the organisms or species are harmed. Limited supply of at least one resource (such as food, water, and territory) used by both can be a factor. Competition both within and between species is an important topic in ecology, especially community ecology. Competition is one of many interacting biotic and abiotic factors that affect community structure. Competition among members of the same species is known as intraspecific. This suggests that reduced aggression of grouped animals may be an acquired result of fighting. Supporting this notion, isolated crickets initially engage in vigorous fights when first grouped, but fighting intensity and duration rapidly decline to the level of life-long grouped crickets within only 10 min. Social isolation is generally reported to lead to increased aggressiveness, while grouping lowers it. We evaluated the effects of varying degrees of isolation and grouping on aggression in a territorial insect, the Mediterranean field cricket, *Gryllus bimaculatus*. The influences of social isolation and crowding on aggression was evaluated from the following groups of experimental animals: Crowded colony.
